                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      or preventing infection. It is also used for imaging HIV-infected tissues (for staging or prognosis of infection, and for assessing efficacy of treatments). The immunoconjugate is also used to determine the HIV envelope glycoprotein burden, once determined, this information is used in the staging and prognosis of HIV infected patients. The immunoconjugate should be active against all strains of HIV (since the CD4-gpl20 interaction is essential for infection). The heterotetramers are assembled intracellularly and secreted efficiently from mammalian cells, allowing high recovery and purification from the culture medium. They have longer half-life in serum and greater avidity than heavy chain
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Sequence
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     immunoconjugate is used to kill cells infected with HIV, and for treating

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     The present invention relates to an immunoconjugate, comprising a cytotoxic radionuclide linked, directly or via a bifunctional chelator, to a heterotetramer having two chimeric CD4-IgG2 heavy chains encoded by an expression vector CD4-IgG2HC-pRCCMV and two chimeric CD4-kappa light chains encoded by an expression vector CD4-kLC-pRcMV. The invention is useful for killing human immunodeficiency virus (HIV)-infected cells, for the treatment and prevention of infection with HIV
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Sequence
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                comprising

                                    The present invention relates to a method for inhibiting infection of a CD4+ cell by HIV. The method comprises contacting the HIV with a CD4-IgG2 chimeric heterotetramer to form a complex with the HIV (CD4 = cluster of differentiation 4; IgG2 = immunoglobulin gamma 2). CD4 is a cell surface glycoprotein that is expressed primarily on the surface of T cells. In man, CD4 is the target of interaction with HIV. The heterotetramer has two heavy and two light chains which are encoded by expression vectors CD4-IgC2HC-PRCCMV (VI) and CD4-KLC-PRCCMV (V2), respectively. The method is used to inhibit infection of a CD4+ cell by a HIV and to prevent CD4+cells of a subject from becoming infected with HIV. The method is also useful for treating a subject having CD4+cells infected with HIV. The prevent CD4-IgG2 chimeric heterotetramer. This sequence was used in the
                                                                                                                                                                                                                                                               Inhibiting human immunodeficiency virus (HIV) infection of a CD4+ or treating a subject having CD4+ cells infected with HIV involves CD4-IgG2 chimeric heterotetramer to form a complex with the HIV.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Human

                                                                                                                                                                                                                                                                                                                                                                                                                                                       The invention relates to a CD4 (cluster of differentiation factor 4) polypeptide ligated at its C-terminus with a portion of an immunoglobulin (Ig) comprising a hinge region and a constant domain of a mammalian Ig heavy chain. The polypeptide comprises a tailpiece from the C-terminus of the heavy chain of an IgA or IgM antibody. Polypeptides of the invention are useful for preparing a composition for treating or preventing human immunodeficiency virus (HIV)-1 infection. The invention is useful in gene therapy and also in the preparation of vaccines. The present sequence is a fusion protein which comprises a human IgA alpha tailpiece (alphatp), a human IgG constant region comprising a hinge, a CH2 and CH3 region and a human CD4 DID2 domain
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       New CD4 polypeptide ligated at its C-terminus with immunoglobulin, useful for preparing a composition preventing HIV-1 infection.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Human; CD4; cluster of differentiation factor 4; immunoglobulin; Ig; human immunodeficiency virus; gene therapy; vaccine; HIV-1 infection; D2; alpha tailpiece; alphatp; fusion protein.

The resulting immunoconjugate comprising the toxin can be used to kill HIV infected cells and to treat HIV infected to reduce the population of HIV infected cells. It can also be used to reduce the population of HIV infected tissue, to convertible the radionuclide can be used to image HIV infected tissue, to calculate the stage of HIV infection or the efficacy of an anti-HIV treatment using the imaging technique and for determining the prognosis of an HIV infected subject.                                                                                                                                   The invention relates to a CD4 (cluster of differentiation factor 4) polypeptide ligated at its C-terminus with a portion of an immunoglobulin (Ig) comprising a hinge region and a constant domain of a mammalian Ig heavy chain. The polypeptide comprises a tailpiece from the C-terminus of the heavy chain of an IgA or IgM antibody. Polypeptides of the invention are useful for preparing a composition for treating or preventing human immunodeficiency virus (HIV)-1 infection. The invention is useful in gene therapy and also in the preparation of vaccines. The present sequence is a fusion protein variant (G218P/L219V/220deLA/G321A) which comprises a human IgA alpha tailpiece (alphatp), a human IgG2 constant region comprising a hinge, a CH2 and CH3 region and a human CD4 DID2 domain. This variant protein is also referred to as mutant F
                                                                                                                                                                                                                                                                                                                                                New CD4 polypeptide ligated at its C-terminus with immunoglobulin, useful for preparing a composition preventing HIV-1 infection.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    /note=

The present sequence is that of fusion protein CD4Pmu comprising the extracellular portion of CD4, which binds to HIV gp120, linked at its C-terminus to the human IgM heavy chain. To obtain the fusion protein, DNA encoding CD4 was linked to IgM DNA at the Pst site upstream of the CH2 region (see AAA50663). Fusion protein CD4Pmu and a nucleic acid encoding it are claimed. Also claimed are a vector comprising the nucleic acid, and a method of producing the fusion protein in secreted form using a transformed host cell. The fusion protein may further comprise a transformed host cell. The fusion protein may further comprise a therapeutic agent, radiolabel or NMR imaging agent. The fusion protein can be administered to an animal (including humans) for treatment of HIV or SIV infection, and can also be used in assays for HIV or SIV, imaging and tissue stains. IgM fusion proteins such as CD4Pmu provide complement-

The fusion protein is capable of being secreted. The fusion proteans are useful for treating HIV or SIV infections in animals, preferably humans. They are also useful for producing medicaments which can be used for treating HIV or SIV infections in humans. The present sequence represents the fusion protein CD4Pmu where the CD4 is linked to human IgG1 at the Pst site upstream of

                                                                                                                                                                                       This invention describes a novel nucleic acid (I) encoding a fusion protein comprising a DNA sequence encoding amino acids 1-173 of CD4 (II) and a DNA sequence encoding a mino acids 1-174 or light chain (III). The products pf the invention have anti-human immunodeficiency virus (HIV) activity and are capable of binding to gpl20. The fusion protein is useful for treating human immunodeficiency virus (HIV) or simian immunodeficiency virus (SIV). This sequence represents the fusion protein CD4Pmu which is constructed from CD4 linked
                                                                                                                Sequence 481
                                                                                                                                                                                                                                                                                                                                                                                                                                            Example 1; Col 49-58; 39pp; English.

The fusion protein genes of the invention pref. comprises cDNA which encode CD4 or a fragment which binds gp120 ligated to an plasmid which encodes an antibody in which the variable region gene has been deleted (see wo87-02671). The CD4 portion of the protein may comprise the complete CD4 sequence, the 370 AA extr

Ig heavy chain is pref. from IgM, IgG1 or IgG3. The following are specifically claimed: fusion proteins CD4Hlambda1, CD4Mmu, CD4Flambda1, and CD4Mmu (No. 67608), pCD4Plambda (No. 67609) and pCD4Elambda1 (No. 67610). It was produced by expression of the coding mutagenised cDNA (produced as described in AAQ28088) in Dhfr-CHO cells. The protein is efficiently assembled intracellularly and effectively secreted from mammalian cells pref. CHO, COS, or myeloma cells as a homodimer, enabling high recovery and purification from the medium of cells expressing it. It possesses increased serum half-life and has increased avidity for HIV of. heavy chain dimers. It can inhibit HIV infection of CD4+ cells and block the spread of HIV infection within a patient. Attachment to a detectable marker makes it useful in an assay for HIV or SIV infection, and it can also be linked to toxins, eg Diphtheria, Pseudomonas extoxin A (domains I or II) or the deglycosylated A-chain of ricin. (Updated on 25-MAR-2003 to correct PN field.) (Updated on 24-OCT-2003 to standardise OS field)

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     δ
        toxin or a gamma radiation-emitting radionuclide of low to moderate cytotoxicity. The resulting immunoconjugate comprising the toxin can be used to kill HIV infected cells and to treat HIV infected subjects to reduce the population of HIV infected cells. It can also be used to reduce the likelihood of infection. The immunoconjugate comprising the radionuclide can be used to image HIV infected tissue, to calculate the stage of HIV infection or the efficacy of an anti-HIV treatment using the imaging technique and for determining the prognosis of an HIV infected subject. The cytotoxic radionuclide is CC linked to either the heavy chains or the light chains, or to all four CC chains, directly or through a bifunctional chelator. Both heavy chains CC linked to either the heavy chains or the light chains are chimeric CD4-kg-CC (ATCC 75193) and both light chains are chimeric CD4-kappa CC chains encoded by vector CD4-kLC-pRcCMV (ATCC 75193) and both light chains are chimeric CD4-kappa CC chains encoded by vector CD4-kLC-pRcCMV (ATCC 75194). CD4 is a non-cc chains encoded by vector CD4-kLC-pRcCMV (ATCC 75194). CD4 is a non-cc chains encoded by vector CD4-kLC-pRcCMV (ATCC 75194). CD4 is a non-cc chains encoded by vector CD4-kLC-pRcCMV (ATCC 75194). CD4 is a non-cc chains encoded by vector CD4-kLC-pRcCMV (ATCC 75194). CD4 is a non-cc complex

                                      The present invention relates to an immunoconjugate, comprising a cytotoxic radionuclide linked, directly or via a bifunctional chelator, to a heterocetramer having two chimeric CD4-IgG2 heavy chains encoded by an expression vector CD4-IgG2NC-PRCCMV and two chimeric CD4-kappa light chains encoded by an expression vector CD4-kLC-pRcMV. The invention is useful for killing human immunodeficiency virus (HIV)-infected cells, for the treatment and prevention of infection with HIV

CD4 is a cell surface glycoprotein that is expressed primarily on the surface of T cells. In man, CD4 is the target of interaction with HIV. The heterotetramer has two heavy and two light chains which are encoded by expression vectors CD4-IgG2HC-pRcCMV (V1) and CD4-kLC-pRcCMV (V2), respectively. The method is used to inhibit infection of a CD4+ cell by a HIV and to prevent CD4+ cells of a subject from becoming infected with HIV. The method is also useful for treating a subject having CD4+ cells infected with HIV. The present sequence is human fusion protein: CD4-gamma2 chimeric heavy chain
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Inhibiting human immunodeficiency virus (HIV) infection of a CD4+ cell, or treating a subject having CD4+ cells infected with HIV involves usin CD4-IgG2 chimeric heterotetramer to form a complex with the HIV.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Sequence
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     The present invention relates to a method for inhibiting infection of a CD4+ cell by HIV. The method comprises contacting the HIV with a CD4-IgG2
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Disclosure;

                                                                   The invention describes a purified CD4-immunoglobulin (Ig)G2 chimeric heterotetramer (I) that neutralises human immunodeficiency virus-1 (HIV-1) having two heavy chains encoded by an expression vector designated CL-IgG2HC-pRcCMV, and two light chains encoded by expression vector designated CD4-kLC-pRcCMV. (I) and a composition (II) comprising (I) or (I) linked to a toxin, are useful for inhibiting HIV infection of a CD4 cell, and preventing a subject being infected with HIV by blocking the spread of HIV infection. This is the amino acid sequence of the CD4-gamma2 chimeric heavy chain of the CD4-IgG2 chimeric heterotetramer useful in inhibiting HIV infection
                                                                                                                                                                                                                                            Novel CD4-immunoglobulin G2 chimeric heterotetramer neutralizes human immunodeficiency virus-1 with two heavy and light chains encoded by expression vectors designated CD4-IgG2HC-pRcCMV and CD4-kLC-pRcCMV,
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         CD4;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Кeу

                                                                                                                                                                                                                                                                                                                                                                                                                                    Query Match
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 This invention describes a novel nucleic acid (I) encoding a fusion protein comprising a DNA sequence encoding amino acids 1-173 of CD4 (II) and a DNA sequence encoding a human immunoglobulin (Ig) heavy or light chain (III). The products pf the invention have anti-human immunodeficiency virus (HIV) activity and are capable of binding to gp120. The fusion protein is useful for treating human immunodeficiency virus (HIV) or simian immunodeficiency virus (SIV). This sequence represents the fusion protein CD4Mg which is constructed from CD4 linked to human IgM upstream of the CH1 region

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     The invention provides a fusion gene encoding a fusion protein that comprises an extracellular CD4 DNA sequence or its fragment which binds to HIV gpl20 when fused to an immunoglobulin (1g) chain and the DNA sequence of an Ig heavy or light chain, where the DNA sequence which encodes the variable region has been replaced with the DNA sequence which encodes extracellular CD4 or its gpl20 binding fragment. The fusion protein is capable of being secreted. The fusion proteins are useful for treating HIV or SIV infections in animals, preferably humans. They are also useful for producing medicaments which can be used for treating HIV or SIV infections in humans. The present sequence represents the fusion protein cD4Mmu where the CD4 is linked to human IgG1 at the Mst2 site upstream of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          14-SEP-1999
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        New fusion gene encoding immunoglobulin-CD4 fusion proteins, useful the treatment of HIV or simian immunodeficiency virus infections.

                                                                                                                                                                                                                                                                                                                               This sequence represents a fusion protein between the CD4 extracellular cd domain and the gamma protein membrane spanning domain and intracellular cd domain. The Fc-receptor-associated gamma chain is expressed in cell surface complexes with additional polypeptides, some of which mediate cligand recognition, and others which have undefined function. Gamma bears a homodimeric structure and overall organisation very similar to that of ceta (see also AAQ28704), and is a component of both the mast cell/basophil high affinity IgE receptor, Fc-epsilon-RI, which consists co fat least three distinct polypeptide chains and one of the low affinity creceptors for IgG, represented in mice by Fc-gamma-RII-alpha. In the production of the CD4 receptor chimera, the gamma cDNA was isolated from the HPB-ALL tumour cell line and from human natural killer cells. The gamma cDNA was joined to the extracellular domain by engineering a BamHI site naturally present a few residues upstream of the membrane spanning domain. (Updated on 25-MAR-2003 to correct PN field.)

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 밁
AAT10801-T10803 represent membrane bound proteinaceous chimeric receptors of the invention. This sequence represents the CD4:eta chimera. The transmembrane region of the chimeric receptor acts to separate the intracellular and extracellular domains of the chimera, and contains a portion of the CD7 (see AAR89440), CD5 or CD34 transmembrane domains. Alternatively, the extracellular portion of the receptor can be separated from the intracellular domain by the hinge, CH2 and CH3 domains of human IgG1 (see AAR89441). The extracellular portion of the chimeric receptor contains a fragment of CD4 (amino acids 1-394 or 1-200 of the CD4 sequence, see AAR89450 and AAR89451) which specifically recognises and binds HIV-infected cells, but does not mediate HIV infection. The extracellular domain of the receptor is separated from the cell membrane by 48 or 72 angstroms, or by one or more proteinaceous alpha-helices. The cells expressing the receptor are preferably T cells, B cells, neutrophils, or dendritic cells. The therapeutic cells expressing the
                                                                                                                                                                                                                                                                                      Membrane-bound chimeric receptor comprising extracellular including CD4 fragment - cells expressing receptor can be treatment of HIV infection.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               The present invention describes DNA encoding a membrane-bound chimeric receptor comprising: (a) an extracellular portion that specifically recognises and binds a target cell or a target infective agent; and (b) an intracellular portion of a T-cell receptor CD3, zeta or eta polypeptide, a B-cell receptor polypeptide or an Fc receptor polypeptide. The present sequence represents a chimeric receptor containing the human eta polypeptide. Cells expressing chimeric receptors of the present invention can be administered to mammals in order to destroy pathogens (e.g. bacteria, fungi, protozoa or viruses, especially HIV), cancer cells
